" Anil Kumar Modify the Registry directly If you have saved the file in a specific folder or you are looking for it on a pen drive or USB, you will probably want to find it easily on other computers. Therefore, you may want to modify the Registry in order to have this app open automatically when you start the computer. Otherwise, Resource.NET allows you to directly modify the Windows Registry, so you will not have to open the file on each computer where you want to keep it. This is a very powerful feature, but it is not supported by the free version. You need to purchase the full version to use it. The procedure is straightforward. You need to browse to the location where you saved the file, for instance, C:\Users\Public\Documents\Resource.NET. When you launch Resource.NET, choose Edit Registry from the menu. Then, press OK to start modifying the registry. If you have any doubts, consult the Registry tutorial provided in this link. Resource.NET provides a Registry tree, which allows you to search for a specific string and add a new key. You can also check if the value exists or not. When you are done, close the app. Resource.NET will stay in the Registry. However, you will need to close it each time you reboot the computer. EDIT: You can also add a startup folder, where Resource.NET will be opened automatically on your startup. This way, you will have this application ready to use as soon as you start your computer. To do that, right-click the startup folder and choose properties from the menu. Then, click the Advanced tab. You will see the Startup folder section, where you need to add the location of 77a5ca646e

## What's New in the Resource .NET?

Resource.NET is a tiny software application that gives you the possibility to update embedded graphic resources in a .NET assembly, as well as to create new ones from scratch. It doesn't need to be installed. No setup required, aside from .NET Framework Provided that you already have. .NET Framework installed on your PC, you can save Resource.NET's files anywhere on the disk and just click the executable to launch the app. Otherwise, you can save it to a pen drive or other removable storage unit, in order to run it on any computer with minimum effort. Unlike most installers, this tool doesn't modify Windows registry settings. Edit images and text strings Resource.NET is wrapped in a classical-looking and intuitive interface, represented by a regular window with a clear-cut structure, where you can indicate the resource type, name and data, as well as add as many resources as you want. Images can be opened from files with the .bmp, .gif, .ico, .jpg, .tif, .emf or .wmf format, while text can be translated into another language. Photos from resource files can be extracted too. Once the project is saved, you can edit data, such as bitmap properties regarding the horizontal and vertical resolution, width and height, pixel and raw format, along with tag. The image can be replaced with another anytime. Resource.NET puts a search function at your disposal for locating strings, together with the possibility to undo and redo your actions. Evaluation and conclusion The tool offers support for multiple instances. It had a good response time and minimal impact on computer performance during our tests, thanks to the fact that it needed low CPU and RAM to work properly. We haven't come across any stability issues, since it didn't hang, crash or prompt error messages. Although Resource.NET is not particularly feature-rich, it delivers a straightforward and effective method to creating and editing resource files, offering support for images and strings. Q: How to send an event to the main thread and wait for it in Java? I'm working on a complex project where I use multiple threads to process a file on a separate thread. After that the file should be processed again by the main thread. I have a processing class which has a run() method which should be called by the main thread. If I call the run() method from the main thread, the run method returns after it has finished its work. But I also want to call it after the file has been processed completely by the other threads. For this I'm using an ExecutorService and an ExecutorCompletionService. The problem is that there seems to be no support for a return value to the main thread, so I need to send an event
